(a) One field of view, two different sets of levels

The feasibility report's claim

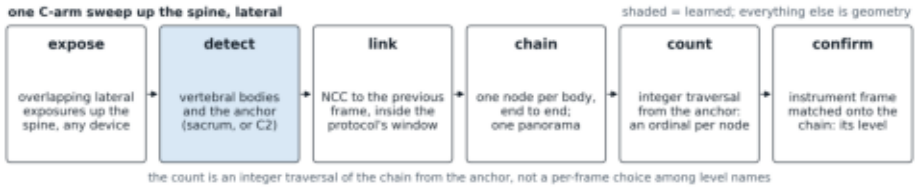

With no anchor in frame (no sacrum, no ribs, no C2), the boxes of a five-lumbar spine look like the boxes of a six-lumbar spine with its top body cropped off:

$P(B \mid M_5) = P(B \setminus b_1 \mid M_6)$

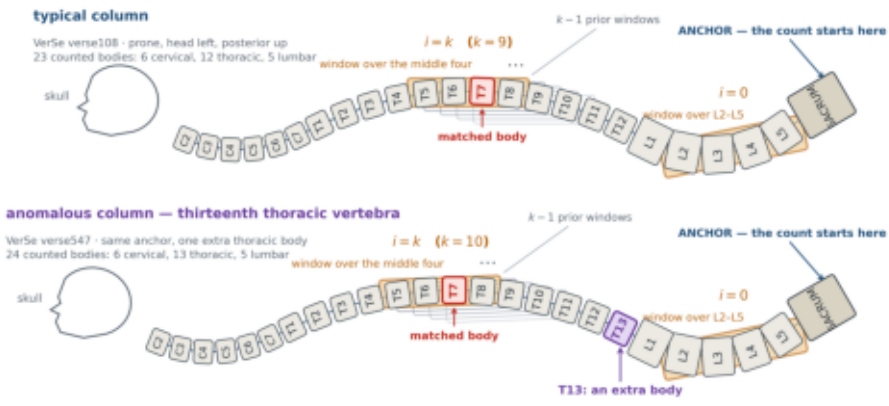

so absolute level assignment is 'mathematically underdetermined' and a system 'should formally refuse to assign absolute anatomical labels'.

What this establishes: no DETERMINISTIC inverse.
What it does not: that no INFORMATION exists.
A posterior is not bound by the first claim.
Whether it is bound by the second is measured in Fig. 2.

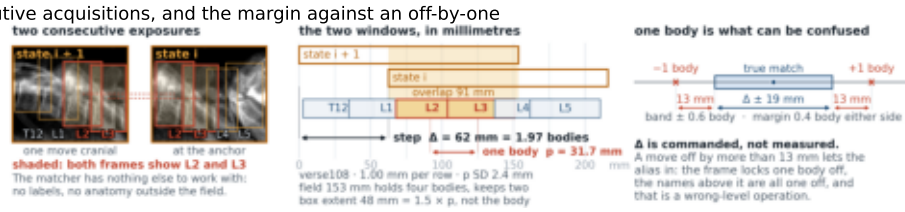

(b) Processing chain

(c) The count up from the sacral anchor, in two states

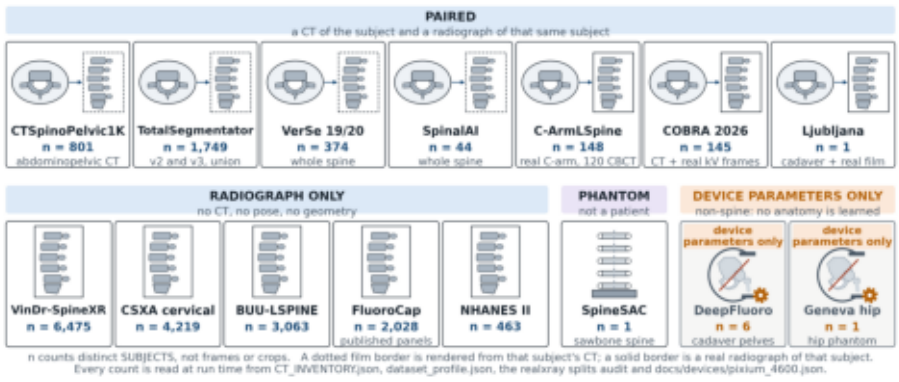

(d) Matching consecutive acquisitions, and the margin against an off-by-one

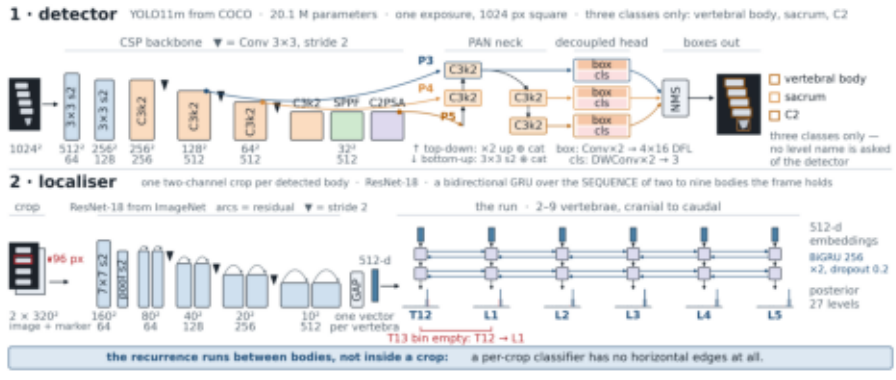

(e) Locating a limited fluoroscopic field on the panorama, and what it reports

(f) The training data

(g) The detector and the localiser

(h) Which local morphology carries level identity
